Understanding Flow Induced Vibrations

Flow induced vibrations are a complex interplay of fluid dynamics and structural mechanics. When a

fluid flows past a structure, it can generate oscillatory forces through various mechanisms, leading to vibrations. These vibrations are classified based on their origin, dominant physical processes, and the nature of the interactions involved. Recognizing these classifications helps engineers predict potential issues and develop effective mitigation strategies.

Classifications of Flow Induced Vibrations

The primary classifications of flow induced vibrations can be broadly divided into vortex-induced vibrations (VIV), Galloping, Wake-induced vibrations, and Turbulence-induced vibrations. Each class encompasses specific phenomena with distinct features, mechanisms, and implications.

Vortex-Induced Vibrations (VIV)

VIV is perhaps the most well-known form of flow induced vibration, occurring when a fluid flow past a bluff body causes the formation of alternating vortices shed from either side of the structure.

Mechanism:

- When fluid flows past a structure, it separates and forms vortices.
- These vortices are shed periodically, creating fluctuating lift forces.
- If the vortex shedding frequency approaches the natural frequency of the structure, resonance occurs, leading to significant vibrations.

Features:

- Typically observed in cylindrical structures such as risers, bridges, and chimneys.
- Exhibits a characteristic Strouhal number that relates vortex shedding frequency, flow velocity, and characteristic dimension.
- Can cause large amplitude oscillations, especially at critical flow velocities.

Pros and Cons:

- Pros:
 - Well-understood phenomenon with extensive empirical data.
 - Allows for predictive modeling and design modifications.
- Cons:
 - Can lead to fatigue failure if not properly damped.
 - Difficult to completely eliminate but can be mitigated through design.

Lessons Learned:

- Incorporate vortex shedding considerations early in design.
- Use damping devices or structural modifications like helical strakes.
- Maintain flow velocities away from critical vortex shedding frequencies.

Wake-induced vibrations occur when the wake of one structure influences neighboring structures, leading to coupled oscillations.

Mechanism:

- Structures placed in close proximity can influence each other's flow fields.
- The alternating vortex shedding from one can excite vibrations in the neighboring structure.
- Often involves resonance between structures with similar natural frequencies.

Features:

- Common in arrays of offshore platforms, heat exchanger tubes, and bridge arrays.
- Highly dependent on spacing, flow velocity, and structural properties.

Pros and Cons:

Turbulence-Induced Vibrations

Turbulence-induced vibrations result from fluctuating turbulent eddies in the flow interacting with the structure.

Mechanism:

- Turbulent flow contains fluctuating velocity components that exert unsteady forces.
- These forces can excite the structure, especially if the turbulence spectrum matches the natural frequencies.
- Typically causes broadband vibrations rather than resonance.

Features:
