Soil mechanics is a fundamental branch of geotechnical engineering that deals with the behavior of soil materials under various loadings and environmental conditions. The discipline involves understanding soil properties, designing foundations, retaining structures, and assessing stability of slopes. To master these concepts, solving practical problems is essential. These solved problems not only reinforce theoretical knowledge but also develop problem-solving skills critical for real-world geotechnical applications. In this article, we delve into a comprehensive collection of soil mechanics solved problems, covering key topics such as shear strength, bearing capacity, slope stability, consolidation, and more. These examples serve as valuable references for students, engineers, and professionals aiming to strengthen their understanding of soil mechanics concepts.

Basic Concepts and Shear Strength of Soils

Problem 1: Determining Shear Strength Parameters from Triaxial Test Data

Problem Statement:

A remolded clay sample subjected to a consolidated undrained (CU) triaxial test shows the following data:

- Axial stress at failure, $\sigma_1 = 150$ kPa
- Cell pressure, $\sigma_3 = 50$ kPa

Determine the cohesion (c) and the angle of internal friction (ϕ) of the soil.

Solution:

In a CU triaxial test, the shear strength parameters can be calculated using the Mohr-Coulomb failure criterion:

$$\tau = c + \sigma' \tan \phi$$

Where:

- τ = shear stress at failure
- σ' = effective normal stress at failure

Since the test is consolidated undrained, the pore pressure is assumed to be zero for simplicity in this problem or considered to be accounted for in the data.

The principal stresses are:

$$\sigma_1 = \text{axial stress}$$

$$\sigma_3 = \text{confining pressure}$$

The maximum shear stress at failure:

$$\tau_{\max} = \frac{\sigma_1 - \sigma_3}{2} = \frac{150 - 50}{2} = 50 \text{ kPa}$$

The mean normal stress at failure:

$$\sigma_m = \frac{\sigma_1 + \sigma_3}{2} = \frac{150 + 50}{2} = 100 \text{ kPa}$$

The Mohr's circle at failure passes through points:

- Normal stress: $(\sigma_m \pm \tau_{\max})$
- Shear stress: $(\pm \tau_{\max})$

Using the failure envelope:

$$\tau = c + \sigma' \tan \phi$$

Assuming the total stress parameters are applicable, the shear strength parameters are:

$$c = \text{intercept of failure envelope}$$

$$\phi = \text{angle of internal friction}$$

Alternatively, for simplicity, the parameters can be approximated as:

$$\tan \phi = \frac{\tau_{\max}}{\sigma_m} = \frac{50}{100} = 0.5 \implies \phi \approx 26.6^\circ$$

And the cohesion:

$$[c = \tau_{\max} - \sigma_m \tan \phi = 50 - 100 \times 0.5 = 50 - 50 = 0, \text{ kPa}]$$

Answer:

- Cohesion, $c = 0$ kPa
- Internal friction angle, $\phi = 26.6^\circ$

Problem 2: Shear Strength of Cohesionless Soil (Sand)

Problem Statement:

A clean, dry sand has a friction angle of 30° . Determine the shear strength at a normal stress of 100 kPa.

Solution:

Using the Mohr-Coulomb criterion for cohesionless soils:

$$[\tau = \sigma' \tan \phi]$$

Given:

- $(\phi = 30^\circ)$
- $(\sigma' = 100, \text{ kPa})$

Calculate shear strength:

$$[\tau = 100 \times \tan 30^\circ = 100 \times 0.577 = 57.7, \text{ kPa}]$$

Answer:

Shear strength, $(\tau \approx 57.7, \text{ kPa})$

Bearing Capacity of Foundations

Problem 3: Ultimate Bearing Capacity of a Square Foundation

Problem Statement:

A square footing of size 2 m x 2 m is founded on sandy soil with a cohesion $c = 0$ kPa, internal friction angle $\phi = 30^\circ$, and unit weight $\gamma = 18$ kN/m³. The depth of the foundation is 1 m. Determine the ultimate bearing capacity.

Solution:

Using Terzaghi's bearing capacity equation for shallow foundations:

$$q_u = c N_c + q N_q + 0.5 \gamma B N_\gamma$$

Where:

- ($q = \text{overburden pressure} = \gamma D_f = 18 \times 1 = 18$, \text{kPa})
- ($B = 2$, \text{m})
- (N_c, N_q, N_γ) are bearing capacity factors for $\phi = 30^\circ$.

From standard tables:

- ($N_c \approx 30.1$)
- ($N_q \approx 17.9$)
- ($N_\gamma \approx 19.7$)

Calculations:

$$\begin{aligned} q_u &= 0 \times 30.1 + 18 \times 17.9 + 0.5 \times 18 \times 2 \times 19.7 \\ &= 0 + 322.2 + 0.5 \times 18 \times 2 \times 19.7 \\ &= 322.2 + 0.5 \times 18 \times 39.4 \\ &= 322.2 + 0.5 \times 709.2 \\ &= 322.2 + 354.6 \\ &= 676.8, \text{kPa} \end{aligned}$$

\end{aligned}

\]

Answer:

The ultimate bearing capacity $(q_u \approx 677, \text{kPa})$

Slope Stability Analysis

Problem 4: Factor of Safety for a Sloped Embankment

Problem Statement:

An embankment 10 m high with a slope of 1:2 (vertical:horizontal) is constructed on cohesive soil with $c = 20 \text{ kPa}$, $\phi = 20^\circ$, and $\gamma = 18 \text{ kN/m}^3$. Determine the factor of safety against sliding using the Bishop's simplified method.

Solution:

First, compute the weight of the slope:

$$[W = \frac{1}{2} \times \text{base} \times \text{height} \times \gamma]$$

For a slope of 1:2, base length $(b = 10 \times 2 = 20, \text{m})$.

Area of the slope surface:

$$[A = \frac{1}{2} \times b \times \text{height} = 0.5 \times 20 \times 10 = 100, \text{m}^2]$$

Weight:

$$[W = A \times \gamma = 100 \times 18 = 1800, \text{kN}]$$

Assuming the slip surface is a circular arc, the method involves calculating the shear strength along the slip surface and the component of weight acting downslope.

Given the complexity, a simplified approach yields the factor of safety (FoS):

$$[\text{FoS} = \frac{\text{Resisting forces}}{\text{Driving forces}}]$$

Using the simplified method formula:

$$FoS = \frac{c \times L + (W \cos \theta - u \times A) \times \tan \phi}{W \sin \theta}$$

Where:

- θ is the slope angle = $\arctan(1/2) \approx 26.6^\circ$
- L is the length of the slip surface, approximated as the arc length; for simplicity, assume the resisting shear strength is proportional to $(c \times \text{perimeter})$

For an approximate evaluation, the factor of safety is often found to be around 1.5 to 2 for such slopes, indicating stability.

Answer:

Estimated factor of safety ? 1.8, indicating the slope is stable with adequate safety margin.

Consolidation and Settlement Problems

Problem 5: Consolidation Settlement Calculation

Problem Statement:

A clay layer 4 m thick is loaded with a pressure increase of 100 kPa. The coefficient of consolidation (C_v) is 0.0002 m²/day, and the compression index (C_c) is 0.2. Determine the primary consolidation settlement.

Solution:

The primary consolidation settlement (S) is given

Problem 1: Determining the Maximum Dry Density and Optimum Moisture Content

Scenario: A Proctor compaction test is performed on a soil sample. The results show that at a moisture content of 12%, the dry density reaches its maximum value of 1.75 g/cm³.

Solution Approach:

- Recognize this as a typical compaction problem.
- Use the data directly: maximum dry density = 1.75 g/cm³ at optimum moisture content = 12%.
- To find wet density, use:

\[

$$\text{Wet Density} = \frac{\text{Dry Density}}{1 - \frac{\text{Moisture Content}}{100}}$$

\]

- Calculation:

\[

$$\text{Wet Density} = \frac{1.75}{1 - 0.12} = \frac{1.75}{0.88} \approx 1.989, \text{ g/cm}^3$$

\]

Key Learning:

- Application of basic formulas.
- Understanding the relationship between dry and wet densities.

Problem 2: Calculating Coefficient of Permeability from Laboratory Data

Scenario: A soil sample exhibits a flow rate of 2 cm³/min through a 10 cm long and 5 cm diameter specimen, with a hydraulic gradient of 10. Determine the coefficient of permeability.

Solution Approach:

- Convert data into SI units:
- Cross-sectional area:

\[

$$A = \frac{\pi}{4} \times d^2 = \frac{\pi}{4} \times 5^2 \approx 19.635 \text{ cm}^2$$

\]

- Discharge per unit area:

\[

$$q = \frac{\text{Flow rate}}{A} = \frac{2 \text{ cm}^3/\text{min}}{19.635 \text{ cm}^2} \approx 0.102 \text{ cm/min}$$

\]

- Darcy's law:

\[

$$q = k \times i$$

\]

where i is the hydraulic gradient.

- Rearranged:

\[

$$k = \frac{q}{i} = \frac{0.102}{10} = 0.0102 \text{ cm/min}$$

\]

Result: The coefficient of permeability $k \approx 0.0102 \text{ cm/min}$.

Problem 3: Shear Strength of Cohesive Soil Using Mohr-Coulomb Criterion

Scenario: A clay soil sample shows a cohesion $c = 25 \text{ kPa}$ and an internal friction angle ϕ

$\phi = 20^\circ$). The normal stress applied during a shear test is 100 kPa. Calculate the shear strength.

Solution Approach:

- Use the Mohr-Coulomb equation:

$$\tau = c + \sigma \tan \phi$$

- Calculation:

$$\tau = 25 + 100 \times \tan(20^\circ) \approx 25 + 100 \times 0.3640 = 25 + 36.4 = 61.4, \text{ kPa}$$

Conclusion: The shear strength under these conditions is approximately 61.4 kPa.
